Description

Dear US help forum,

I merged the files of BHPS and UKHLS. When I did my computations, I noticed that there is an amazing increase in the number of proxy respondents between UKHLS and BHPS.

In my sample, which contains singles who may or not transition to cohabitation or marriage, missing values increase from 3,79% in the last wave of BHPS up to 9,85% in the first wave of UKHLS (and the trend in the following years is increasing).

Is there an explanation for this significant growth in the relative share of proxy respondents?

Thank you and best regards,
Lydia

The variable which I am mostly concerned about is the one regarding savings (b`w'_save and `w'_save). It presents quite a high amount of proxy respondents and I cannot understand if this is related to a particular routing of the questionnaire, to a problem occurred in the sample or whether I am doing something wrong. Thank you and best,
Lydia

Dear Lydia,

The straightforward answer is that it was much more difficult to get all household members to cooperate in the survey when Understanding Society started in 2009 than it was when BHPS started in 1991, and once people got into the habit of responding it was easier to keep them in. So it reflects general population changes in willingness to participate in surveys, and we would rather have some proxy data than no data.

If the question is asked of proxies then that answer will be in the data, but for all questions not asked of proxies, the code will be -7.

Best wishes,
Stephanie Auty - Understanding Society User Support Officer
