Description			
Hello,			
I am a PhD student at the Centre for Health Economics at University of York.			
I am currently using BHPS dataset and I encounter an issue with the variable wFIHHMN: household income, month before the interview.			
It seems that this variable has some observations (634) with income zero and others with very low income per month, i.e. less than £10. I have read the BHPS documentation regarding the no imputation of the data on those households where no individual interviews were completed and I thought those zeros might correspond to those cases. However, BHPS usually assigns negative values (i.e. -9, -2, etc.) to those cases instead of zeros.			
Therefore, I was wondering whether is there any explanation on why there are entire households with income zero?			
Thanks, Irene.

A part from households with genuinely low incomes some households may be reluctant to report incomes in general. See also the advice given here: [#330](#)
